

# Connected Components and Correctness of BFS in SSSP

CSCI 2100 Teaching Team

## Outline

Today's tutorial covers:

- finding connected components;
- proving that BFS correctly solves the unit-weight SSSP problem.

## Connected Components

**Problem:** Let  $G = (V, E)$  be an undirected graph. Our goal is to compute all the **connected components** (CC) of  $G$ .

A CC of  $G$  includes a set  $S \subseteq V$  of vertices such that:

- (Connectivity) any two vertices in  $S$  are reachable from each other;
- (Maximality) it is not possible to add another vertex to  $S$  while still satisfying the above requirement.

Output:

$\{a, b, c, d, f\}, \{g, e\}, \{h, i, j, k\}$

## A Lemma on CCs

**Lemma 1:** Take an arbitrary vertex  $s$ . The CC of  $s$  is the set  $S$  of vertices in  $G$  reachable from  $s$ .

### Proof:

- Connectivity: any two vertices in  $S$  can reach each other via  $s$ .
- Maximality: any vertex outside  $S$  is unreachable from  $s$ .

## A BFS Solution

1. Run BFS on  $G$  starting from a white source vertex
2. Output the vertex set of the BFS-tree
3. If there is still a white vertex in  $G$ , repeat from 1

BFS-forest

## Proof of Correctness

**Claim:** The vertex set  $S$  of every BFS-tree is a CC of  $G$ .

**Proof:** Follows immediately because BFS finds all the vertices reachable from  $s$ . □

## A DFS Solution

1. Run DFS on  $G$  starting from a white source vertex
2. Output the vertex set of the DFS-tree
3. If there is still a white vertex in  $G$ , repeat from 1

DFS-forest

## Proof of correctness

**Claim:** The vertex set  $S$  of each DFS-tree is a CC of  $G$ .

**Proof:** Let  $s$  be the source vertex of DFS. We will show that the DFS-tree contains all and only the vertices reachable from  $s$ .

Let  $v$  be a vertex reachable from  $s$ . At the beginning of DFS, there is a white path from  $s$  to  $v$ . By the white path theorem,  $v$  must be in the subtree of  $s$ , namely, in the DFS-tree.

It is obvious that every vertex in the DFS-tree is reachable from  $s$ .

□

## Single Source Shortest Path (SSSP) with Unit Weights

Let  $G = (V, E)$  be a directed graph, and  $s$  be a vertex in  $V$ . The goal of the **SSSP problem** is to find, for **every** other vertex  $t \in V \setminus \{s\}$ , a shortest path from  $s$  to  $t$ , unless  $t$  is unreachable from  $s$ .

## Using BFS to Solve SSSP Problem

Run BFS algorithm starting from  $s$  on  $G$ , which returns a **BFS-tree**  $T$ .

For any  $v \in V \setminus \{s\}$ , report the path from  $s$  to  $v$  in  $T$  as the shortest path from  $s$  to  $v$  in  $G$ .

## Proof of Correctness

We first prove a useful lemma.

**Lemma 2:** For any two vertices  $u, v \in V$  such that  $u \neq v$ , if  $l(u) < l(v)$ , it must hold that  $u$  is enqueued before  $v$  during the BFS.

**Proof:** We will prove this by induction.

**Base Case.**  $l(u) < l(v) \leq 1$ .

We must have  $l(u) = 0$  and  $l(v) = 1$ , which means  $u$  is the source  $s$ . As  $s$  is enqueued at the very beginning of BFS,  $s$  is enqueued before  $v$ . The base case holds.

## Inductive Case.

**Inductive assumption:** For any two vertices  $u, v$  satisfying  $l(u) < l(v) \leq L - 1$  where  $L \geq 2$ , it always holds that  $u$  is enqueued before  $v$ .

Consider any vertices  $u$  and  $v$  satisfying  $l(u) < l(v) = L$ . Let  $p_u$  and  $p_v$  be their parents in the BFS-tree  $T$ , respectively. We have  $l(p_u) = l(u) - 1$  and  $l(p_v) = l(v) - 1$ .

It follows that  $l(p_u) < l(p_v) \leq L - 1$ . By the inductive assumption,  $p_u$  is enqueued before  $p_v$ . From the FIFO property of queue,  $p_u$  is dequeued before  $p_v$ . As  $u$  (resp.,  $v$ ) is enqueued right after  $p_u$  (resp.,  $p_v$ ) is dequeued,  $u$  is enqueued before  $v$ .

We now prove the correctness of BFS.

**Theorem:** For any vertex  $v \in V$ , the path from  $s$  to  $v$  in  $T$  is a shortest path from  $s$  to  $v$  in  $G$ .

We will prove a stronger claim by induction:

**Claim:** If a vertex  $v \in V$  has shortest path distance  $L$  from  $s$ , then  $l(v) = L$ .

**Base Case.**  $L = 0$  or  $1$ .

- $s$  is the only vertex with shortest path distance 0 from  $s$ . It is obvious that  $l(s) = 0$ .
- Every vertex  $v$  with shortest path distance 1 from  $s$  will be enqueued when  $s$  is dequeued and thus has  $l(v) = 1$ .

## Inductive Case.

**Inductive assumption:** If a vertex  $v$  has shortest path distance  $L \leq k - 1$  from  $s$  where  $k \geq 2$ , then  $l(v) = L$ .

Let  $v$  be a vertex with shortest path distance  $k$  from  $s$ . Consider all the shortest paths from  $s$  to  $v$  and let  $U$  denote the set of predecessors of  $v$  in those paths. Furthermore, let  $u_1$  denote the vertex in  $U$  that was enqueued the earliest. The shortest path distance from  $s$  to  $u_1$  is  $k - 1$ .

By the induction assumption,  $l(u_1) = k - 1$ . To prove  $l(v) = k$ , it suffices to prove that  $v$  is enqueued at the moment  $u_1$  is dequeued, namely,  $v$  is still white when  $u_1$  is dequeued. We will prove this by contradiction.

Suppose that when  $u_1$  is dequeued,  $v$  is not white.

Define  $w$  as the parent of  $v$  in  $T$  (i.e.,  $v$  is enqueued after  $w$  is dequeued). By Lemma 2, We have  $l(w) \leq l(u_1)$  as  $w$  is dequeued before  $u_1$ . We further have  $l(w) \neq l(u_1)$ ; otherwise,  $w$  must belong to  $U$ , which contradicts the definition of  $u_1$ .

It follows that  $l(w) < l(u_1)$ . However, this means that the shortest path distance from  $s$  to  $w$  is less than  $k - 1$ . Thus, the shortest path distance from  $s$  to  $v$  is less than  $k$ , giving a contradiction.
