You will use CSIM as a simulation tool to solve the following problems. Also, if possible, verify with the theoretical result (if available). Last but not least, in all your result, you need to specify ALL necessary parameters for your simulation.

1. Simulate a $M/M/1$ system. Plot the
   (a) average number of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).
   (b) average response time of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).

   In your simulation, you need to allow the user to input i) average arrival rate, ii) average service time, iii) number of jobs for the simulation.

2. Simulate a $M/E_3/1$ system. The density function of the service time is:
   \[ b(x) = \frac{3\mu(3\mu x)^2e^{-3\mu x}}{2!} \quad x \geq 0 \]

   Plot the
   (a) average number of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).
   (b) average response time of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).

   In your simulation, you need to allow the user to input i) average arrival rate, ii) average service time, iii) number of jobs for the simulation.

3. Simulate a bulk arrival system (e.g., the one that we discussed in class). Let the bulk arrival process be Poisson and the service time of each job be exponentially distributed. Let $g_i$ be the probability that the arrival bulk size is $i$. We have:
   \[ g_1 = 0.5; g_2 = 0.25, g_3 = 0.25 \]

   Plot the
   (a) average number of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).
   (b) average response time of jobs for $\rho$, the system utilization, between 0.1 to 0.95 (with increment size of 0.05).

   In your simulation, you need to allow the user to input i) average bulk arrival rate, ii) average service time, iii) number of jobs for the simulation. (Warning: be careful of stability).
4. Simulate a closed queueing network. Assume that we have 4 nodes $n_i, i = 1, 2, 3, 4$. For node $n_4$, it has an exponential service rate of $\mu_i$. We have $\mu_1 = 2.0, \mu_2 = 4.0, \mu_3 = 3.0, \mu_4 = 10.0$. The job routing is:

\[
\begin{align*}
  p_{1,2} &= 0.5 \\
  p_{1,3} &= 0.5 \\
  p_{2,1} &= 0.5 \\
  p_{2,3} &= 0.5 \\
  p_{3,4} &= 1.0 \\
  p_{4,1} &= 0.5 \\
  p_{4,2} &= 0.2 \\
  p_{4,4} &= 0.3
\end{align*}
\]

Let $N = 10$ be the number of jobs in the closed queueing network. Find:

(a) The average number of jobs in node $n_i, i = 1, 2, 3, 4$.

(b) The average throughput in node $n_1$.

In your simulation, make sure that I can alter different values of $\mu_i$ and $N$.
