# Authentication

- Server knows your password
- They may impersonate you at other websites where you use the same password

# Zero-knowledge authentication

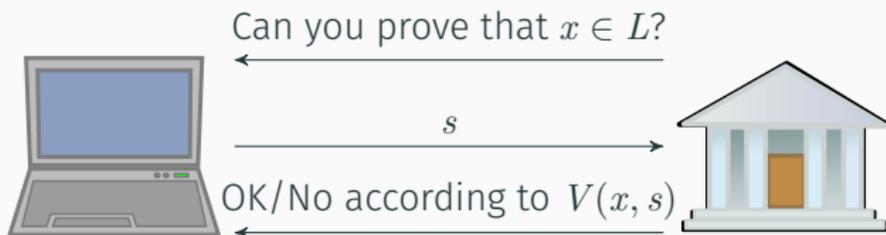

Can you convince the server that you know your password, without revealing it?

# NP and proofs

Recall that a language  $L$  is in NP if

there is a polynomial-time verifier  $V$  such that  
 $x \in L$  if and only if  $V$  accepts  $(x, s)$  for some  $s$

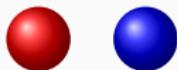

$s$  is a **proof** that  $x \in L$

Verifier  $V$  is convinced that  $x \in L$ , but verifier also knows a lot more

# A protocol for non-color-blindness

You want to convince me you are **not color-blind**

I pull at random either a red ball or a blue ball and show it to you

You say **red** or **blue**

We repeat this 10 times

If you got all the answers right

I am convinced you can tell apart red from blue

# Interaction and knowledge

What **knowledge** did I gain from this interaction?

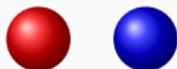

I learned that you can tell apart red from blue

But I also learned the colors of the balls

If I were color-blind

Then I used you to gain some **knowledge** that I didn't have

# A different protocol

I pull at random either a red ball or a blue ball and show it to you

We repeat 10 times

Each time (except the first)

you say “same color as previous” or “different color from previous”

If you got all the answers right

I am convinced you can tell apart red from blue

But I did not gain other knowledge!

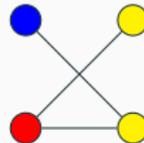

Suppose I am color-blind but you are not

In the first experiment, I cannot **predict** your answer ahead of time

In the second one, I **know** what you are supposed to say, so I do not gain knowledge when you say it

# Graph Coloring

**Task:** Assign one of 3 colors to the nodes so that every edge has different colors at its endpoints

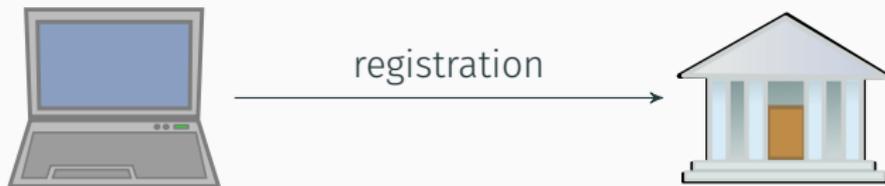

$$3\text{COL} = \{\langle G \rangle \mid \text{Graph } G \text{ has a valid 3-coloring}\}$$

3COL is NP-complete

Goldreich–Micali–Wigderson proposed a zero-knowledge protocol for 3COL

# GMW protocol: Choosing a password

password is a random string of colors

$$\Sigma = \{\text{blue}, \text{red}, \text{yellow}\}$$

e.g. password = yellow red blue red red blue

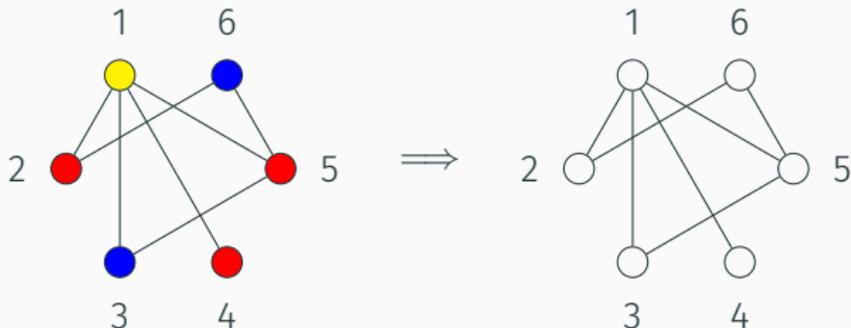

# GMW protocol: Commitment phase

Instead of sending the password to the server  
you **construct** a graph with vertices colored as in password

Put some (random) edges between vertices of different colors

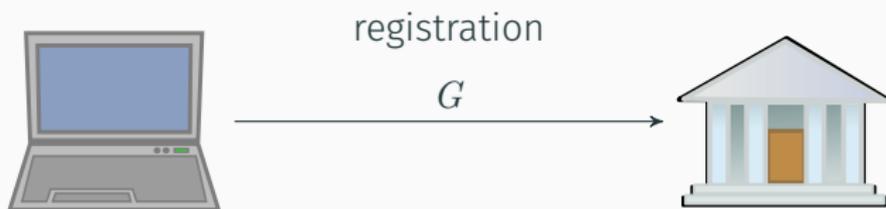

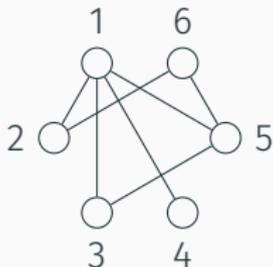

Delete the colors of the vertices

# GMW protocol: Commitment phase

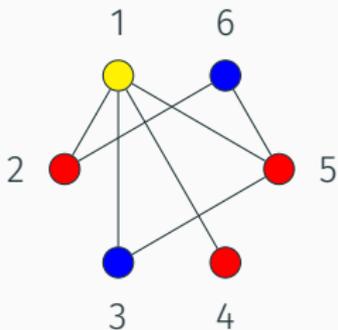

Your **real password** is the **coloring**, which you hide from the server

You give the server a graph  $G$  that you know how to color, but the server doesn't

Since 3COL is NP-hard, the server shouldn't be able to figure out your coloring (password) from  $G$

## GMW protocol: Login phase

You randomly **permute** the colors

You **lock** each of the colors in an imaginary box

**Send** the locked boxes to server

Server picks a random edge and **asks for keys** to the related boxes

You **send** the two requested keys

The server **unlocks** two boxes and checks the colors are different

Repeat all of the above steps 1000 times

If colors are always different, login succeeds

Why can't an impostor log in instead of you?

An impostor does not know how to color the graph

Some edge will be colored improperly

When the server asks to see this edge, impostor will be detected

# GMW protocol: Zero-knowledge

Why doesn't the server **learn** your password?

When you send the password, the server can only see some locked boxes

The server then asks you to unlock some boxes

Colors in the password were **shuffled**, so server will only see **two random colors**

How do you send boxes and keys over the internet?

Commitment scheme!

## Other proposed applications

1. Zero-knowledge voting
2. Zero-knowledge nuclear warhead verification
