

# CMSC5706 Topics in Theoretical Computer Science

## Week 12: Quantum computing

Instructor: Shengyu Zhang

# Roadmap

- Intro to math model of quantum mechanics
- Review of quantum algorithms
- The power of quantum computers.
- Quantum games.

# Postulate 1: States

- *State space*: Every isolated physical system corresponds to a unit vector in a complex vector space.
  - Unit vector:  $\ell_2$ -norm is 1.
- Such states are called **pure states**.
- We use a weird “**ket**” notation  $|\cdot\rangle$  to denote such a state.

# Ket notation

- Mathematically,  $|\cdot\rangle$  is a column vector.
- And  $\langle\cdot|$  is a row vector.
- $\langle\psi|\phi\rangle$  is the inner product between the vectors  $|\phi\rangle$  and  $|\psi\rangle$ .
- $\langle\psi|M|\psi\rangle$  is just the quadratic form  $\psi^T M \psi$ .

- A quantum bit, or qubit, is a state of the form

$$\alpha|0\rangle + \beta|1\rangle$$

where  $\alpha, \beta \in \mathbb{C}$  are called **amplitudes**, satisfying that  $|\alpha|^2 + |\beta|^2 = 1$ .

- So a qubit can sit anywhere between 0 and 1 (on the unit circle).
- We say that the state is in **superposition** of  $|0\rangle$  and  $|1\rangle$ .

A quantum bit  
(qubit)

# Postulate 2: operation

- *Evolution*: The evolution of a closed quantum system is described by a unitary transformation.
- That is, if a system is in state  $|\psi_1\rangle$  at time  $t_1$ , and in state  $|\psi_2\rangle$  at time  $t_2$ , then there is a unitary transformation  $U$  s.t.

$$|\psi_2\rangle = U|\psi_1\rangle.$$

- Unitary transformation:  $U^\dagger = U^{-1}$ 
  - Recall:  $U^\dagger = (U^T)^*$ , transpose + complex conjugate
  - You can think of it as a **rotation** operation.

# Postulate 3: measurement

- *Measurement: We can only observe a quantum system by measuring it.*
- The outcome of the measurement is **random**.
- And the system is **changed** by the measurement.

- If we measure qubit  $\alpha|0\rangle + \beta|1\rangle$  in the computational basis  $\{|0\rangle, |1\rangle\}$ , then outcome “0” occurs with prob.  $|\alpha|^2$ , and outcome “1” occurs with prob.  $|\beta|^2$ .
- The system becomes  $|0\rangle$  if outcome “0” occurs, and becomes  $|1\rangle$  if outcome “1” occurs.
  - The system collapses.

A quantum bit  
(qubit)

# Measurement on general states

- In general, an **orthogonal measurement** of a  $d$ -dim state is given by an orthonormal basis  $\{|\psi_1\rangle, \dots, |\psi_d\rangle\}$ .
- If we measure state  $|\phi\rangle$  in basis  $\{|\psi_1\rangle, \dots, |\psi_d\rangle\}$ , then outcome  $i \in \{1, \dots, d\}$  occurs with prob.  $|\langle\phi|\psi_i\rangle|^2$ .
- The system collapses to  $|\psi_i\rangle$  if outcome  $i$  occurs.

# Postulate 4: composition

- Composition: The state of the joint system  $(S_1, S_2)$ , where  $S_1$  is in state  $|\psi_1\rangle$  and  $S_2$  in  $|\psi_2\rangle$ , is  $|\psi_1\rangle \otimes |\psi_2\rangle$ .
- $\otimes$ : tensor product of vectors.
  - $(a_1, a_2) \otimes (b_1, b_2, b_3) = (a_1b_1, a_1b_2, a_1b_3, a_2b_1, a_2b_2, a_2b_3)$ .
  - $\dim(|\psi_1\rangle \otimes |\psi_2\rangle) = \dim(|\psi_1\rangle) \cdot \dim(|\psi_2\rangle)$
  - $\text{size}(|\psi_1\rangle \otimes |\psi_2\rangle) = \text{size}(|\psi_1\rangle) + \text{size}(|\psi_2\rangle)$ 
    - size: number of qubits.
- Notation:  $|0\rangle^{\otimes n} = |0\rangle \otimes \cdots \otimes |0\rangle$ ,  $n$  times.

Composition

Tensor Product

A quantum bit (qubit)

Classical:

Quantum:

State space for 2 bits:  
combinations  $\{00,01,10,11\}$

State space for 2 qubits:  
space  $\text{span}\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$

# Density matrix

- If a system is in state  $|\psi_1\rangle$  with probability  $p_1$ , and in state  $|\psi_2\rangle$  with probability  $p_2$ , then the system is in a **mixed state**.
- The mixed state is represented as a **density matrix**

$$\rho = p_1|\psi_1\rangle\langle\psi_1| + p_2|\psi_2\rangle\langle\psi_2|.$$

- In general, if a system is in state  $|\psi_i\rangle$  with probability  $p_i$ , then the mixed state is

$$\rho = \sum_i p_i |\psi_i\rangle\langle\psi_i|$$

- For pure state  $|\psi\rangle$ ,  $\rho = |\psi\rangle\langle\psi|$ .

# Density matrix

- **Fact.** A matrix  $\rho$  is a density matrix of some mixed quantum state iff
  - $\rho$  is **positive semi-definite** (psd)
  - $\text{Tr}(\rho) = 1$ .
- **Recall:**
  - A matrix  $M$  is psd if all its eigenvalues are nonnegative. Equivalently, if  $\langle v|M|v\rangle \geq 0, \forall v$ .
  - The trace of a matrix  $M$  is  $\text{Tr}(M) = \sum_i M_{ii}$ .

# Postulates on mixed states

- Unitary operation  $U$ :  $\rho \mapsto U\rho U^\dagger$ 
  - For pure state  $\rho = |\phi\rangle\langle\phi|$ , it becomes  $U\rho U^\dagger = U|\phi\rangle\langle\phi|U^\dagger = |\phi'\rangle\langle\phi'|$  where  $|\phi'\rangle = U|\phi\rangle$ .
- Orthogonal measurement  $\{|\psi_1\rangle, \dots, |\psi_d\rangle\}$ : outcome  $i$  occurs with probability  $|\langle\psi_i|\rho|\psi_i\rangle|^2$ , and the system collapses to  $\rho' = |\psi_i\rangle\langle\psi_i|$ .
  - For pure state  $\rho = |\phi\rangle\langle\phi|$ , the probability is  $|\langle\phi|\psi_i\rangle|^2$ , and the collapsed state is  $|\psi_i\rangle$ .
- If we measure  $\rho \in \mathbb{C}^{d \times d}$  in the computational basis  $\{|1\rangle, |2\rangle, \dots, |d\rangle\}$ , then  $\text{Pr}[\text{outcome } i \text{ occurs}] = \rho_{ii}$ , the  $i$ -th diagonal entry of  $\rho$ .

- Composition of  $\rho_1$  and  $\rho_2$  is just  $\rho_1 \otimes \rho_2$ 
  - For pure state  $\rho_1 = |\phi_1\rangle\langle\phi_1|$  and  $\rho_2 = |\phi_2\rangle\langle\phi_2|$ , the joint state is
 
$$|\phi_1\rangle\langle\phi_1| \otimes |\phi_2\rangle\langle\phi_2|$$

$$= (|\phi_1\rangle \otimes |\phi_2\rangle)(\langle\phi_1| \otimes \langle\phi_2|)$$
- Recall tensor product of matrices:

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \otimes \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\ a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\ a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\ a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22} \end{bmatrix}$$

- For operation, measurement and composition, these formulas for mixed states are all consistent to what we learned for pure states.
- So the formulas for mixed states extend those for pure states.

# entanglement

- Consider the following **EPR pair** state in a 2-qubit system:  $\frac{|00\rangle + |11\rangle}{\sqrt{2}}$

- It's in superposition of  $|00\rangle$  and  $|11\rangle$ .
- There is no classical counterpart of this.

- *Question: Is it really different than the classical correlation*

$$\begin{cases} 00 & \text{with prob. } 1/2 \\ 11 & \text{with prob. } 1/2 \end{cases} \quad ?$$

# CHSH non-local game

- $x \in_R \{0,1\}, y \in_R \{0,1\}$
- Goal: A outputs  $s$  and B outputs  $t$  s.t.  
$$s \oplus t = x \cdot y$$
- Value = largest  $\Pr[s \oplus t = x \cdot y]$ .
- Classical value:  $3/4 = 0.75$ .
  - Even with shared randomness.
- Quantum value:  $\frac{1}{2} + \frac{1}{2\sqrt{2}} \approx 0.85$ 
  - By sharing an EPR pair.

$$s \oplus t = x \cdot y ?$$

# Roadmap

Shor: Factoring  
& Discrete Log

QFT

(Quantum Fourier Transform): exponential speedup; slower than expected.

- Factoring: Given an  $n$ -bit number, factor it (into product of two numbers).
- Classical (best known) :  $O\left(2^{n^{1/3}}\right)$
- Quantum\*1:  $O(n^2)$

\*1: P. Shor. *STOC'93*, *SIAM Journal on Computing*, 1997.

# Area 1: Quantum Algorithms

- Implication of fast algorithm for Factoring
  - Theoretical: Church-Turing thesis
  - Practical: Breaking RSA-based cryptosystems

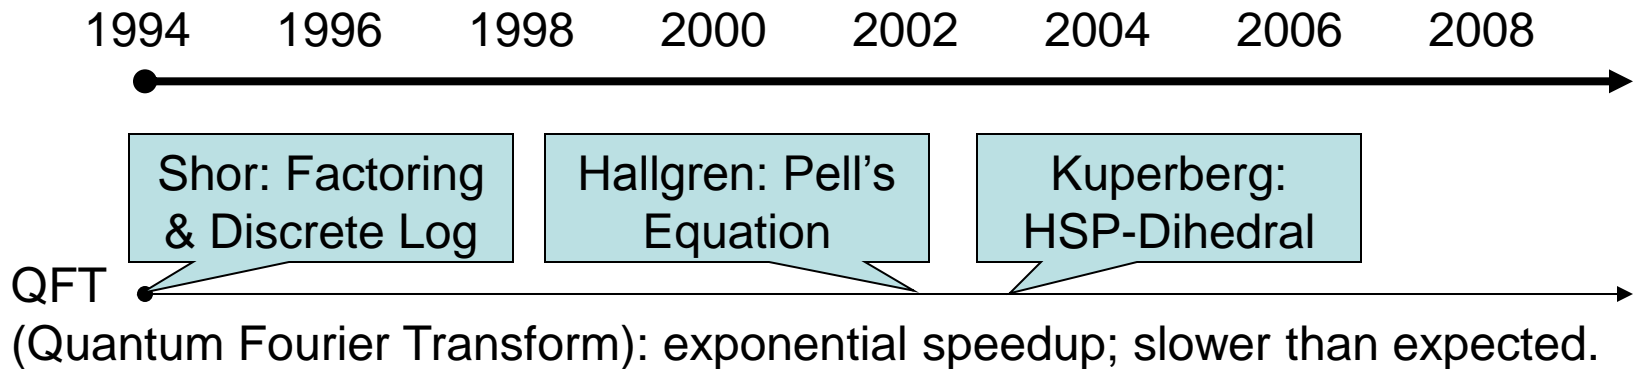

# Area 1: Quantum Algorithms

- Pell's Equation:  $x^2 - ny^2 = 1$ .
- Problem: Given  $n$ , find solutions  $(x, y)$  to the above equation.
- Classical (best known):
  - $\sim 2^{\sqrt{\log n}}$  (assuming the generalized Riemann hypothesis)
  - $\sim n^{1/4}$  (no assumptions)
- Quantum<sup>\*1</sup>:  $\text{poly}(\log n)$ .

\*1: S. Hallgren. *STOC'02. Journal of the ACM*, 2007.

# Area 1: Quantum Algorithms

- Hidden Subgroup Problem (HSP): Given a function  $f$  on a group  $G$ , which has a hidden subgroup  $H$ , s.t.  $f$  is
  - constant on each coset  $aH$ ,
  - distinct on different cosets.Task: find the hidden  $H$ .
- Factoring, Pell's Equation both reduce to it.
- Efficient quantum algorithms are known for Abelian groups.
- Main question: HSP for non-Abelian groups?

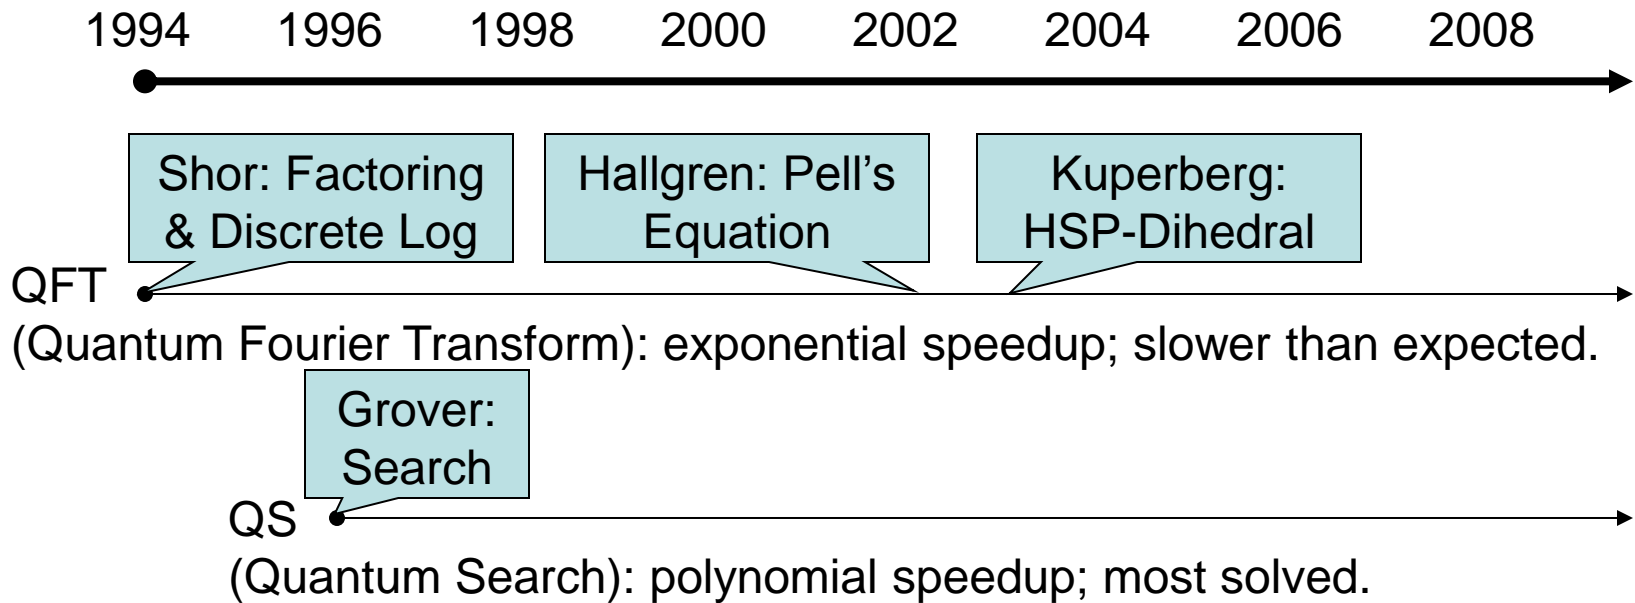

# Area 1: Quantum Algorithms

- Two biggest cases:
  - HSP for symmetric group  $S_n$ : Graph Isomorphism reduces to it.
  - HSP for dihedral group  $D_n$ : Shortest Lattice Vector reduces to it.
- $HSP(D_n)$ :
  - Classical (best known):  $2^{\log |G|}$
  - Quantum\*1:  $2^{O(\sqrt{\log |G|})}$

\*1: G. Kuperberg. arXiv:quant-ph/0302112, 2003.

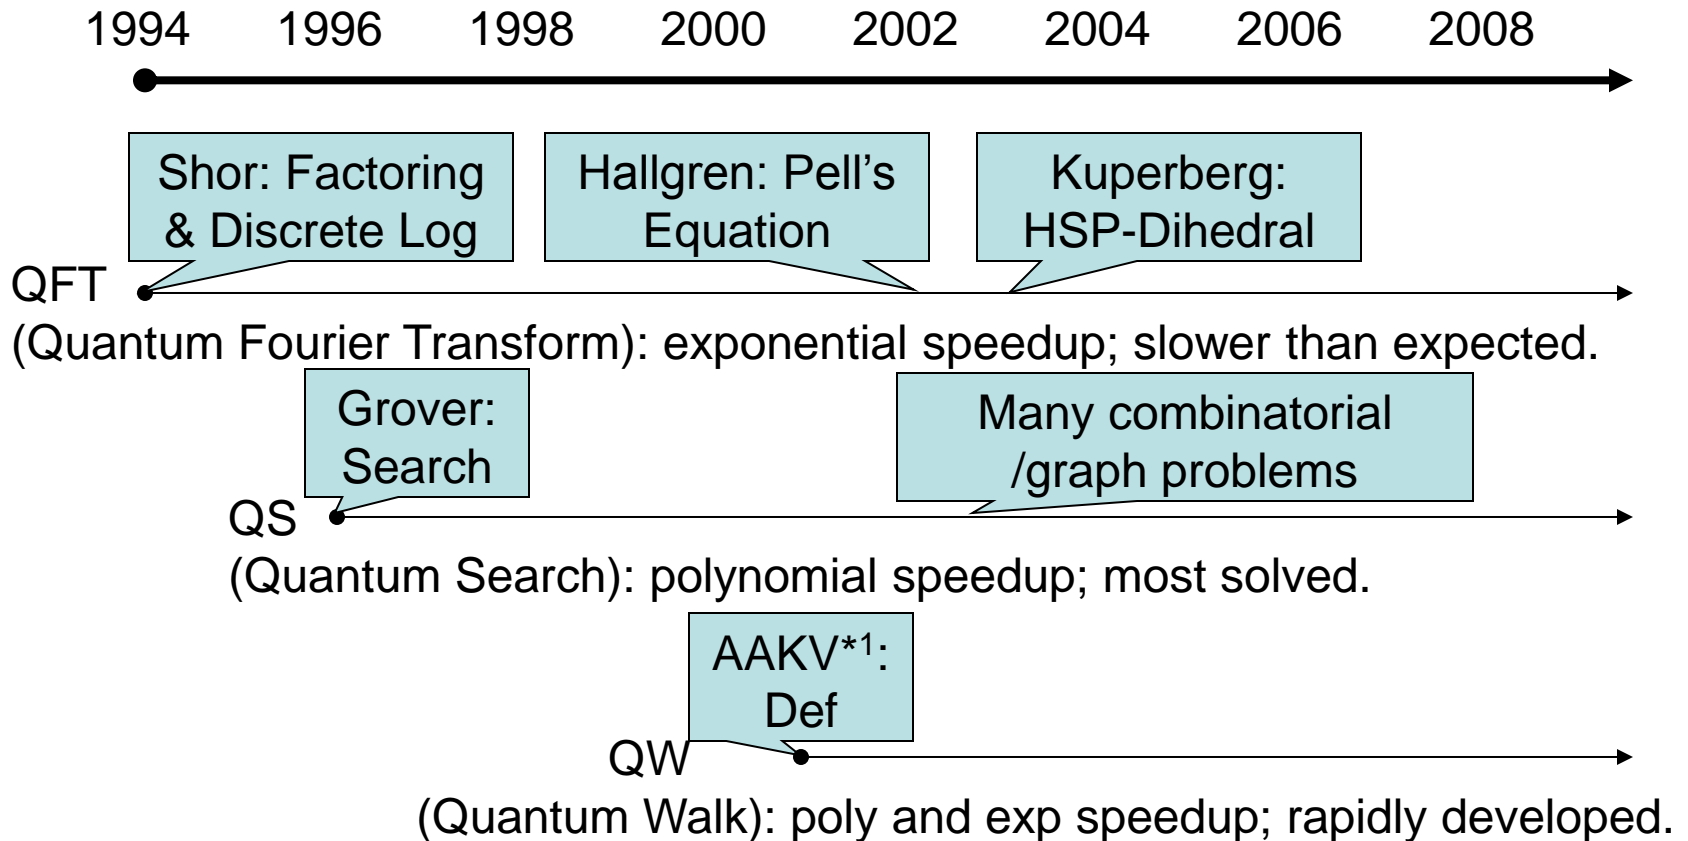

# Area 1: Quantum Algorithms

- Given  $n$  bits  $x_1, \dots, x_n$ , find an  $i$  with  $x_i = 1$ .
- Classical:  $\Theta(n)$
- Quantum\*1:  $\Theta(\sqrt{n})$

1994      1996      1998      2000      2002      2004      2006      2008

- Classical random walk on graphs: starting from some vertex, repeatedly go to a random neighbor
  - Many algorithmic applications
- Quantum walk on graphs: even definition is non-trivial.
  - For instance: classical random walk converges to a stationary distribution, but quantum walk doesn't since unitary is reversible.

# Roadmap

- Intro to math model of quantum mechanics
- Review of quantum algorithms
- **The power of quantum computers.**
- Quantum games.

# Power of quantum computing

- *Question: How powerful is quantum computer?*
- P: problems solvable in **polynomial time**
  - One characterization of efficient computation
- BPP: problems solvable in **probabilistic polynomial time** w/ a small error tolerated
  - Another characterization of efficient computation
- BQP: problems solvable in polynomial time by a quantum computer w/ a small error tolerated
  - Yet another characterization of efficient computation, if you believe large-scale quantum mechanics.

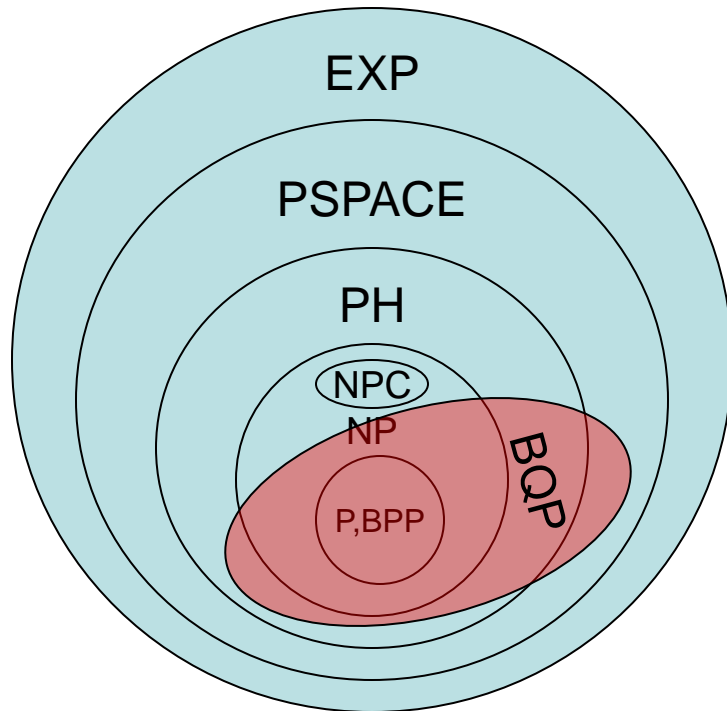

# Classical upper bound of BQP

- Central in complexity theory: **comparison** of different modes of computation
- How to compare **classical** and **quantum** efficient computation?
- Quantum is more powerful:  **$BPP \subseteq BQP$**
- An upper bound (of quantum by classical)
- [Thm\*<sup>1</sup>]  **$BQP \subseteq PSPACE$** 
  - PSPACE: problems solvable in polynomial space.
  - Believed to be much larger than NP.

\*1: Bernstein, Vazirani. *STOC'93, SIAM J. on Computing*, 1997

# Where does BQP sit in?

- BQP contains BPP and P.
- But it probably doesn't contain all NP.
- Yet it's possible to be outside PH.
- It's position may be weird.

# Roadmap

- Intro to math model of quantum mechanics
- Review of quantum algorithms
- The power of quantum computers.
- **Quantum games.**

# Meyer's game: classical

- Actions  $A_i, B_i$ :  
to flip or not to flip
- Alice's Goal: 0. Bob's Goal: 1.
- A Nash equilibrium:  $A_i, B_i$  flip with half prob.
  - Then each wins with half prob.

# Meyer's game: quantum

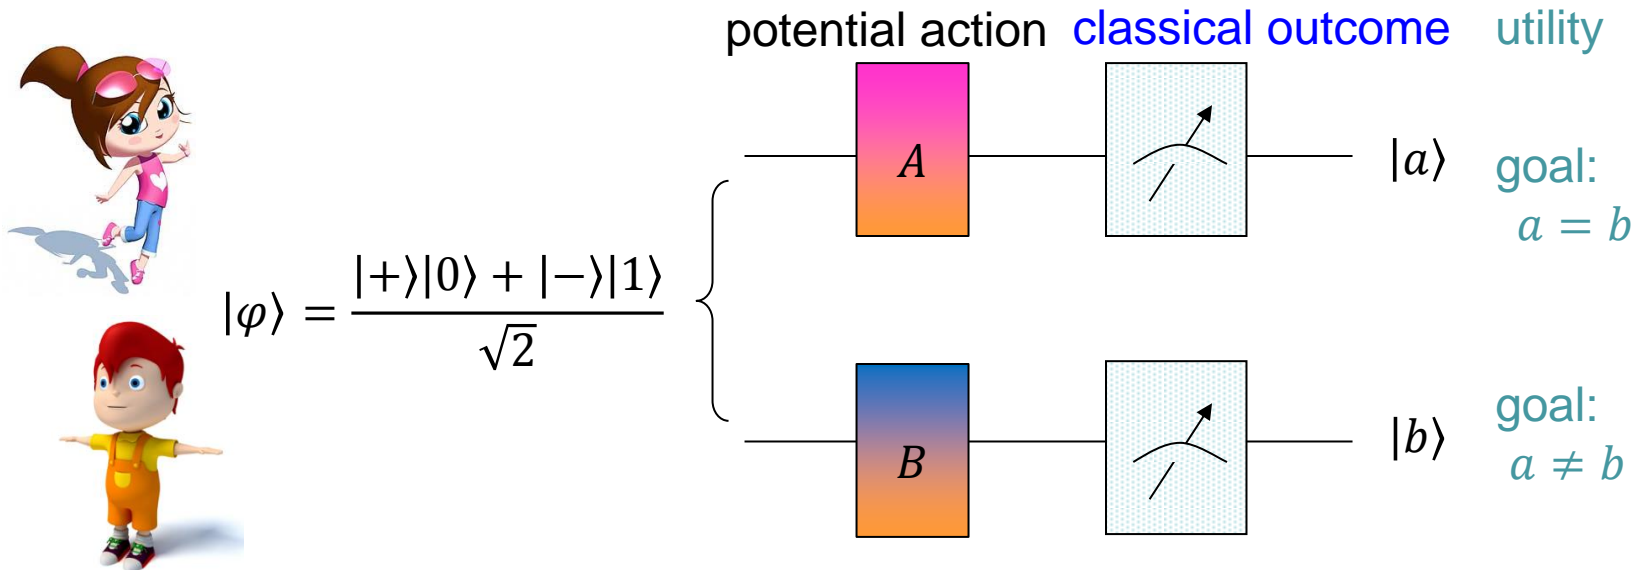

- Bob remains **classical**:  $B_1$  is either  $X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  (Swap  $|0\rangle$  and  $|1\rangle$ ) or identity (doing nothing).
- Alice is **quantum**:  $A_i$  can be any 1-qubit operation.
- Alice's Goal:  $|0\rangle$ . Bob's Goal:  $|1\rangle$ .
- Now Alice can **win for sure** by applying a Hadamard gate.  $A_1: |0\rangle \rightarrow |+\rangle$ .  $A_2: |+\rangle \rightarrow |0\rangle$ .

# Meyer's game: fairness issue

- Despite the quantum advantage, there is clear a fairness issue.
  - Alice has two actions.
  - And the actions are in a fixed order of  $A_1 \rightarrow B_1 \rightarrow A_2$ .
- *Question: Can quantum advantage still exist in a more fair setting?*
- For fairness: each player makes just **one** action, **simultaneously**.
  - This is nothing but strategic games!

# Quantization\*<sup>1</sup> of strategic game: Penny Matching

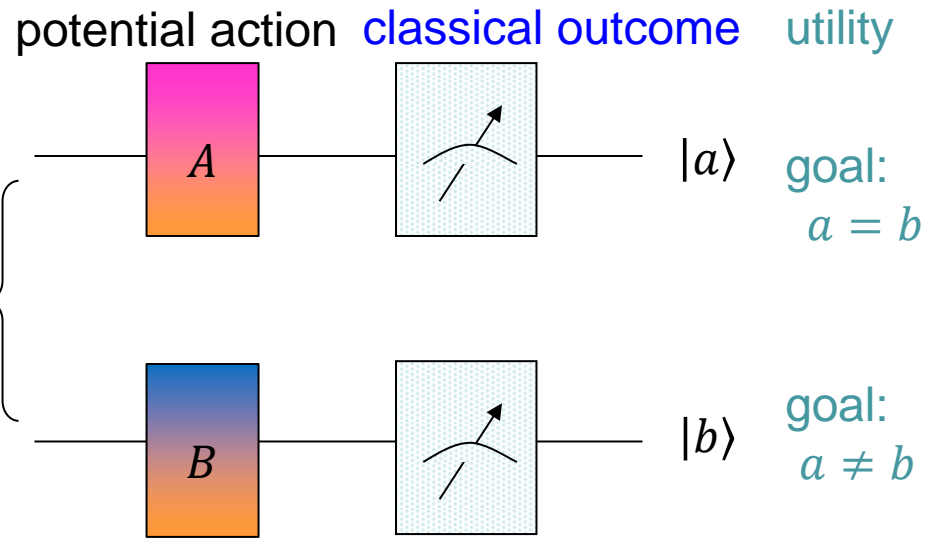

- $|\varphi\rangle$  is an equilibrium if both players are classical,
  - Each wins with half prob.
- If Alice turns to quantum:  $A = H$  turns  $|\varphi\rangle$  into  $\frac{|0\rangle|0\rangle + |1\rangle|1\rangle}{\sqrt{2}}$ . Then she wins for sure!
- *Message: quantum player has a huge advantage when playing against a classical player.*

\*1. Zu, Wang, Chang, Wei, Zhang, Duan, NJP, 2012.

# Quantization of strategic game: Penny Matching

$$\begin{aligned}
 |\varphi\rangle &= \frac{|+\rangle|0\rangle + |-\rangle|1\rangle}{\sqrt{2}} \\
 &= \frac{|0\rangle|+\rangle + |1\rangle|-\rangle}{\sqrt{2}}
 \end{aligned}$$

- State is symmetric, so it doesn't matter who takes which qubit.
- We can also let the classical player Bob to choose the target goal.
  - If Bob wants  $a = b$ , then Alice applies  $XH$ .

# Quantum advantage in strategic games

$$|\varphi\rangle = \frac{|+\rangle|0\rangle + |-\rangle|1\rangle}{\sqrt{2}}$$

Entangled.  
Necessary?

No!  $\rho = \frac{1}{4} \left( \begin{array}{l} |+\rangle\langle +| \otimes |0\rangle\langle 0| + |0\rangle\langle 0| \otimes |+\rangle\langle +| \\ + |-\rangle\langle -| \otimes |1\rangle\langle 1| + |1\rangle\langle 1| \otimes |-\rangle\langle -| \end{array} \right)$

No entanglement.  
But has discord.

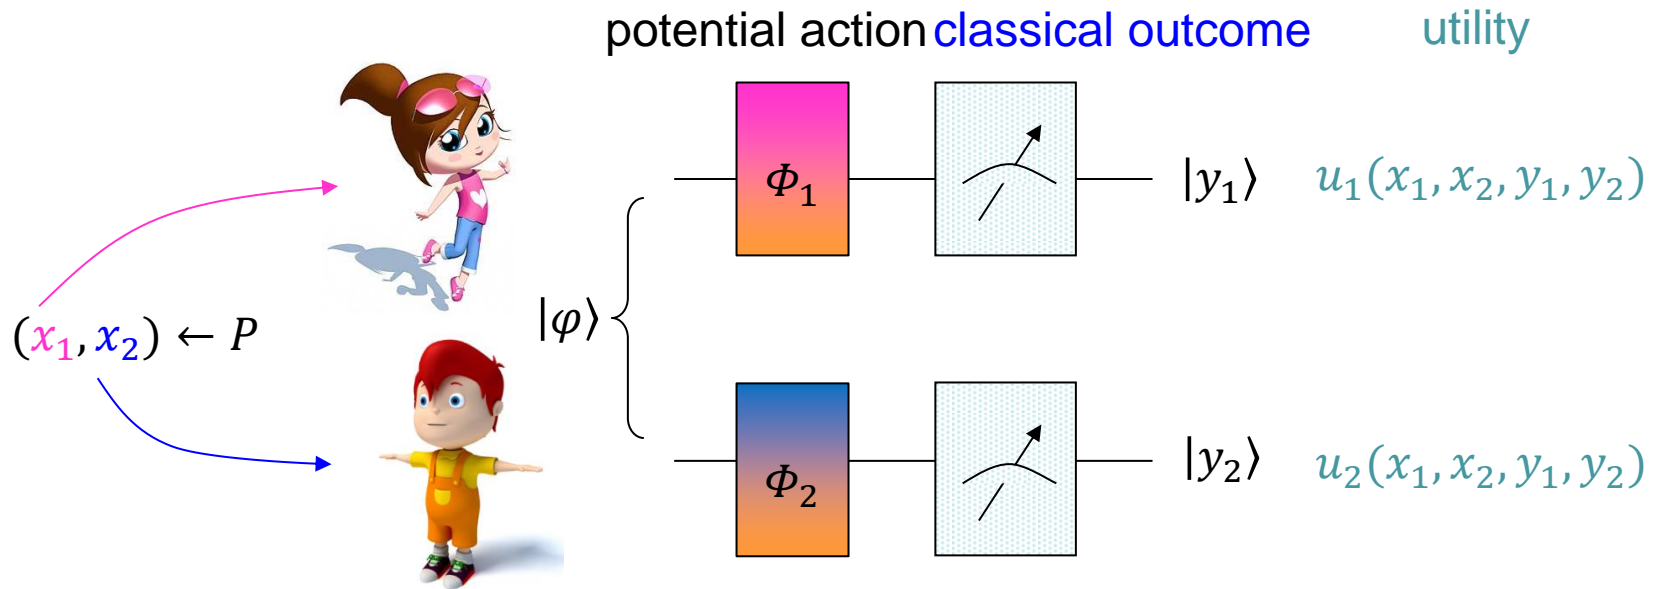

- $\rho$  is an equilibrium if both players are classical, each winning with prob. =  $\frac{1}{2}$
- If Alice uses quantum,  $A = H$  increases her winning prob. to  $\frac{3}{4}$ .
- **Question\*2**: *Is discord necessary?*
  - Yes, if each player's part (of the shared state) is a qubit,
  - No, if each player's part (of the shared state) has dimension 3 or more.

\*2. Wei, Zhang, TAMC, 2014.

# Games between quantum players

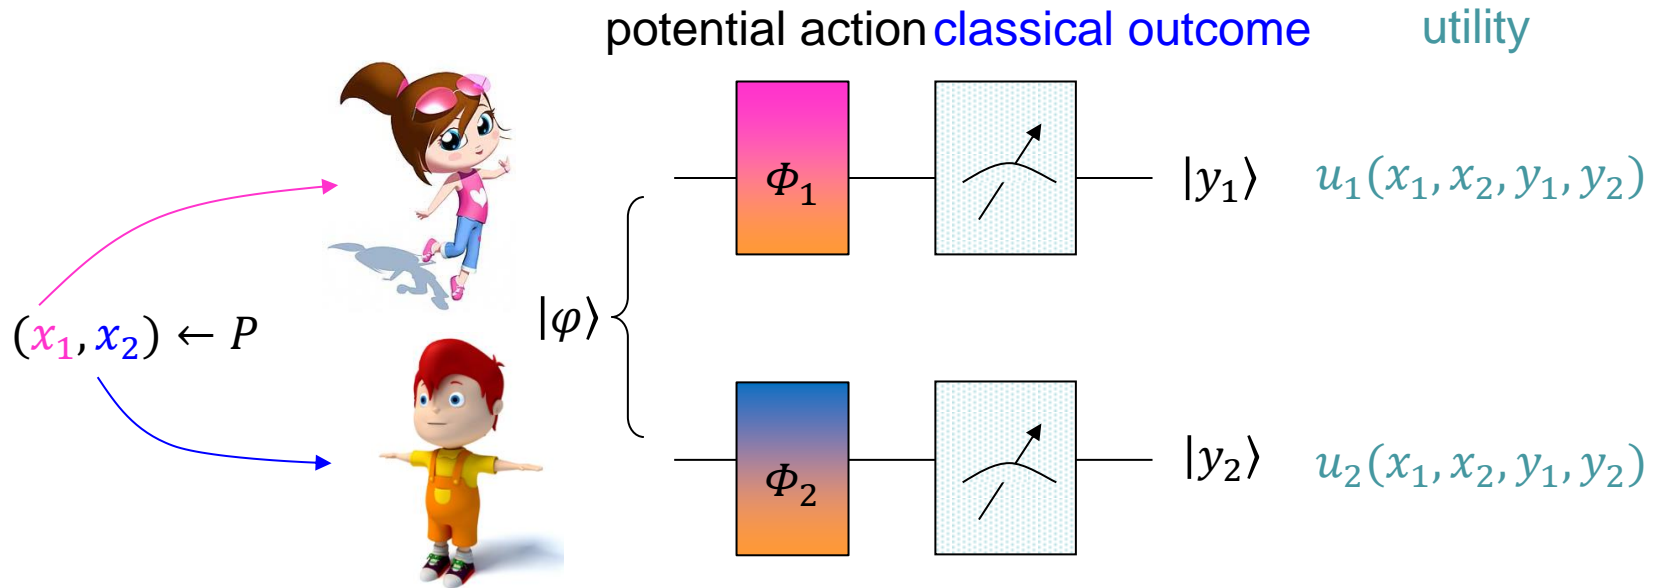

- After these examples, Bob realizes that he should use quantum computers as well.
- *Question: Any advantage when both players are quantum?*
- Previous correspondence results imply a negative answer for complete information games.
- But quantum advantage exists for **Bayesian games!**

# Quantum Bayesian games

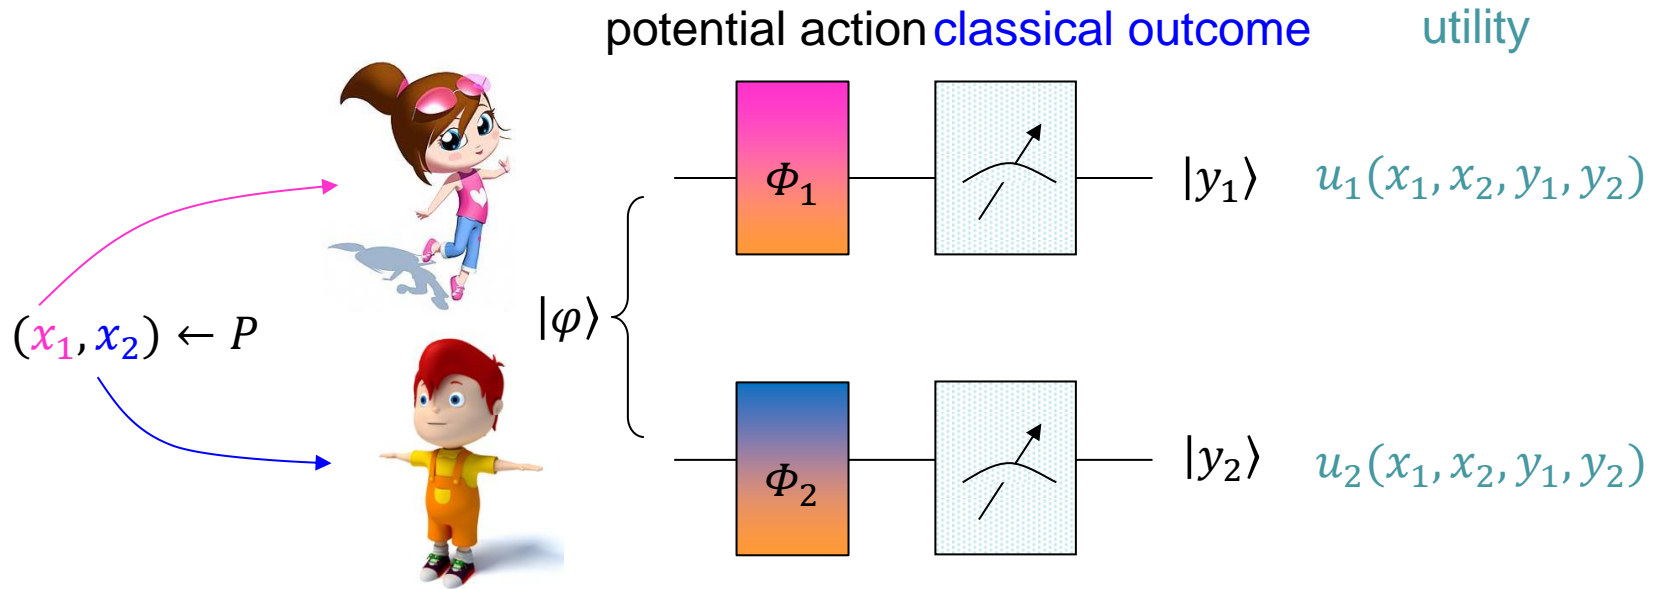

- Each player  $i$  has a private input/type  $x_i$ .
  - $x_i$  is known to Player  $i$  only.
  - The joint input is drawn from some distribution  $P$ .
- Each player  $i$  can potentially apply some operation  $\Phi_i$ .
- A measurement in the computational basis gives output  $|y_i\rangle$  for Player  $i$ , who receives utility  $u_i(x_1, x_2, y_1, y_2)$ .

# Quantum Bayesian games

- Classical state  $|\varphi\rangle = (r_1, r_2) \leftarrow$  distribution  $Q$ .
- Classical strategy  $\Phi_i = c_i(x_i, r_i)$ .
- Classical payoff
 
$$\mathbf{E}[u_i] = \mathbf{E}_{x \leftarrow P, r \leftarrow Q} [u_i(x, c_1(x_1, r_1), c_2(x_2, r_2))]$$
- $(Q, c_1, c_2)$  is equilibrium if no player can gain a higher payoff by changing her strategy unilaterally.

# Quantum Bayesian games

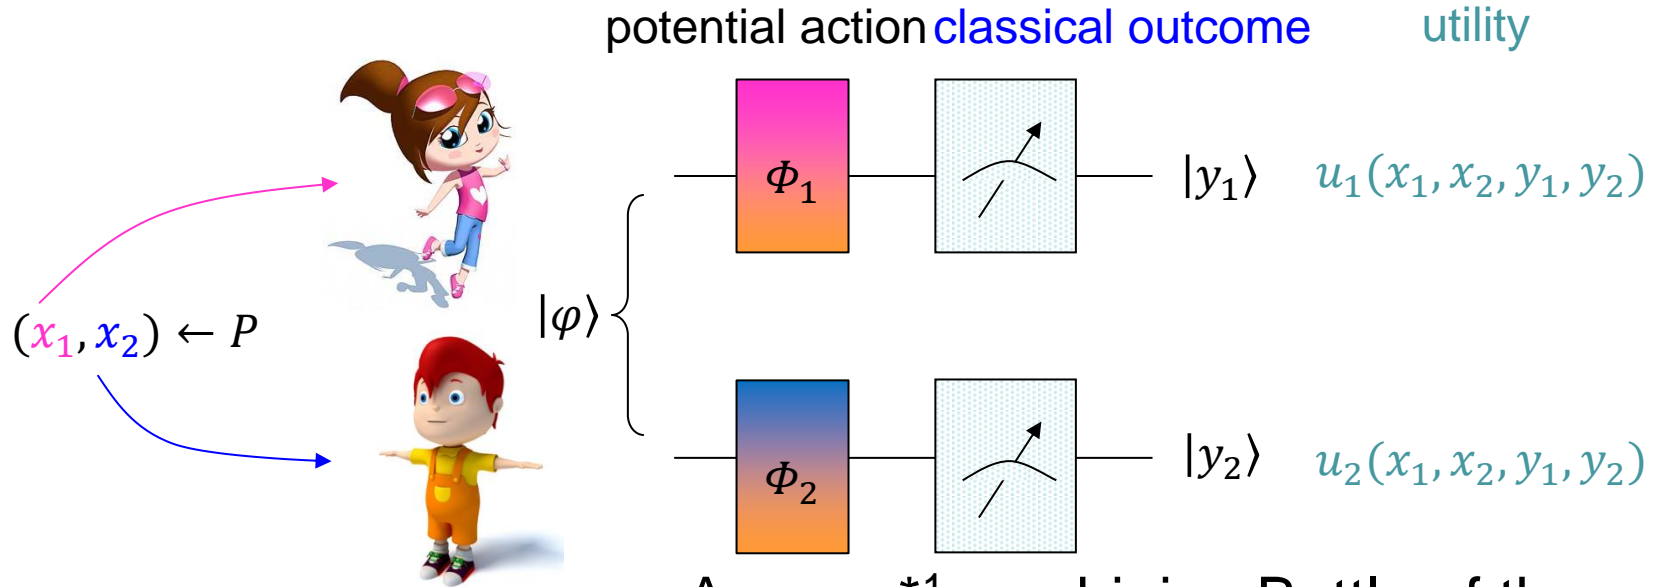

- Quantum strategy  $\Phi_1 = \{E_{x_1}^{y_1} : E_{x_1}^{y_1} \geq 0, \sum_{y_1} E_{x_1}^{y_1} = I\}$ ,  $\Phi_2 = \{F_{x_2}^{y_2} : F_{x_2}^{y_2} \geq 0, \sum_{y_2} F_{x_2}^{y_2} = I\}$ .

- Quantum payoff

$$\mathbf{E}[u_i] = \mathbf{E}_{x \leftarrow P} [\langle \varphi | E_{x_1}^{y_1} \otimes F_{x_2}^{y_2} | \varphi \rangle \cdot u_i(x, y)]$$

- $(|\varphi\rangle, \Phi_1, \Phi_2)$  is equilibrium if no player can gain a higher payoff by changing her strategy unilaterally.

# Quantum Bayesian games

	$y_B = 0$	$y_B = 1$
$y_A = 0$	(1,1/2)	(0,0)
$y_A = 1$	(0,0)	(1/2,1)

Table I:  $x_A \wedge x_B = 0$

	$y_B = 0$	$y_B = 1$
$y_A = 0$	(0,0)	(3/4,3/4)
$y_A = 1$	(3/4,3/4)	(0,0)

Table II:  $x_A \wedge x_B = 1$

- A game\*<sup>1</sup> combining Battle of the Sexes and CHSH.
- The players need to coordinate like in CHSH, except when  $x_1 = x_2 = 1$ , in which case they need to anti-coordinate.
- In Table I, they have conflicting interest.

\*1. Pappa, Kumar, Lawson, Santha, Zhang, Diamanti, Kerenidis, *PRL*, 2015.

# Quantum Bayesian games

	$y_B = 0$	$y_B = 1$
$y_A = 0$	(1, 1/2)	(0, 0)
$y_A = 1$	(0, 0)	(1/2, 1)

Table I:  $x_A \wedge x_B = 0$

	$y_B = 0$	$y_B = 1$
$y_A = 0$	(0, 0)	(3/4, 3/4)
$y_A = 1$	(3/4, 3/4)	(0, 0)

Table II:  $x_A \wedge x_B = 1$

- $P$  is uniform.
- Classical:  $u_1 + u_2 \leq 9/8$ .  
And  $\exists$  a fair equilibrium with  
 $u_1 = u_2 = 9/16 = 0.5625$ .
- Quantum:  $\exists$  a fair equilibrium with  
 $u_1 = u_2 = (3/4) \cos^2(\pi/8) \approx 0.64$

\*1. Pappa, Kumar, Lawson, Santha, Zhang, Diamanti, Kerenidis, *PRL*, 2015.

# Viewed as non-locality

- Traditional quantum non-local games exhibit quantum advantages when the two players have the common goal.
  - CHSH, GHZ, Magic Square Game, Hidden Matching Game, Brunner-Linden game.
- Now the two players have conflicting interests.
- Quantum advantages still exist.
- *Message: If both players play quantum strategies in an equilibrium, they can also have advantage over both being classical.*

# Summary

- Quantum algorithms: offer huge speedup for certain computational problems.
- Quantum entanglement:
  - A distinctive feature of quantum mechanics.
  - Proof that our world is quantum mechanical.
- Quantum games: quantum players can have big advantages.
