# Probability models

---

A **probability model** is an assignment of probabilities to every element of the sample space.

Probabilities are nonnegative and add up to one.

## Examples

$$\mathcal{S} = \{ \text{HH}, \text{HT}, \text{TH}, \text{TT} \}$$
$$\frac{1}{4} \quad \frac{1}{4} \quad \frac{1}{4} \quad \frac{1}{4}$$

models a pair of coins with **equally likely outcomes**

# Elements of a Probabilistic Model

---

- **Event**: a subset of sample space.
  - $A \subseteq \Omega$  is a set of possible outcomes
  - *Example*.  $A = \{HH, TT\}$ , the event that the two coins give the same side.
- The **probability law** assigns our knowledge or belief to an event  $A$  a number  $P(A) \geq 0$ .
  - It specifies the likelihood of any outcome.

# Probability Axioms

---

1. (*Non-negativity*)  $P(A) \geq 0$ , for every event  $A$ .
2. (*Additivity*) For any two disjoint events  $A$  and  $B$ ,  $P(A \cup B) = P(A) + P(B)$   
In general, if  $A_1, A_2, \dots$  are disjoint events, then  
$$P(A_1 \cup A_2 \cup \dots) = P(A_1) + P(A_2) + \dots$$
3. (*Normalization*)  $P(\Omega) = 1$ .

# De Morgan's laws

---

$$(A \cup B)^c = A^c \cap B^c \qquad (A \cap B)^c = A^c \cup B^c$$

$A^c$

$B^c$

$A^c \cup B^c$

$$(A_1 \cup \cdots \cup A_n)^c = A_1^c \cap \cdots \cap A_n^c$$

$$(A_1 \cap \cdots \cap A_n)^c = A_1^c \cup \cdots \cup A_n^c$$

# Question

---

Bonferroni's inequality.

Prove that for any two events  $A$  and  $B$ , we have

$$P(A \cap B) \geq P(A) + P(B) - 1$$

$$P(A) + P(B) - P(A \cap B) = P(A \cup B)$$

$$P(A \cup B) \leq 1$$

# Question

---

Romeo and Juliet have a date.

Each will arrive at the meeting place with a delay between 0 and 1 hour, with all pairs of delays being equally likely.

The first to arrive will wait for 15 minutes and will leave if the other has not yet arrived.

*Question:* What is the probability that they will meet?

# Question

---

Sample space: the unit square  $[0,1] \times [0,1]$ ,

Its elements are the possible pairs of delays.

“equally likely” pairs of delays: let  $P(A)$  for event  $A \subseteq \Omega$  be equal to  $A$ ’s “area”.

This satisfies the axioms.

$$M = \left\{ (x, y) : |x - y| \leq \frac{1}{4}, 0 \leq x \leq 1, 0 \leq y \leq 1 \right\}$$

# Question

---

The event that Romeo and Juliet will meet is the shaded region.

Its probability is  
calculated to be  $7/16$ .  
 $= 1 - \text{the area of the}$   
 $\text{two unshaded triangles}$   
 $= 1 - 2 \cdot \left(\frac{3}{4}\right) \cdot \left(\frac{3}{4}\right) / 2$   
 $= 7/16$ .

$$M = \left\{ (x, y) : |x - y| \leq \frac{1}{4}, 0 \leq x \leq 1, 0 \leq y \leq 1 \right\}$$

# Question

---

A parking lot contains 100 cars,  $k$  of which happen to be lemons. We select  $m$  of these cars at random and take them for a test drive. Find the probability that  $n$  of the cars tested turn out to be lemons.

The sample space

$$\Omega = \{\text{random choose } m \text{ cars}\}$$

The size of sample space

$$|\Omega| = \binom{100}{m}$$

# Question

---

A parking lot contains 100 cars,  $k$  of which happen to be lemons. We select  $m$  of these cars at random and take them for a test drive. Find the probability that  $n$  of the cars tested turn out to be lemons.

The event  $n$  cars are lemons ( $n \leq k$  and  $n \leq m$ )

$$\binom{k}{n} \cdot \binom{100-k}{m-n}$$

The probability

$$P = \binom{k}{n} \cdot \binom{100-k}{m-n} / \binom{100}{m}$$

## Question: Conditioning

- Consider **ten** independent rolls of a 6-sided die. Let  **$X$**  be the number of **6**s and let  **$Y$**  be the number of **1**s obtained.
- What is the joint PMF of  $X$  and  $Y$ ?
- $X$  is a binomial random variable with  $n = 10$  and  $p = \frac{1}{6}$
- $P(Y = b|X = a)$  is a binomial random variable with  $n = 10 - a$  and  $p = \frac{1}{5}$
- So the joint PMF is

$$\begin{aligned} P(X = a, Y = b) &= P(X = a)P(Y = b|X = a) \\ &= \binom{10}{a} \left(\frac{1}{6}\right)^a \left(\frac{5}{6}\right)^{10-a} \binom{10-a}{b} \left(\frac{1}{5}\right)^b \left(\frac{4}{5}\right)^{10-a-b} \end{aligned}$$

# Total Probability Theorem

- Let  $A_1, A_2, \dots, A_n$  be **disjoint** events that form a **partition** of the sample space. Assume  $P(A_i) > 0$  for all  $i$ . Then, for any event  $B$ , we have

$$\begin{aligned} P(B) &= P(A_1 \cap B) + \dots + P(A_n \cap B) \\ &= P(A_1)P(B|A_1) + \dots + P(A_n)P(B|A_n) \end{aligned}$$

- Indeed,  $B$  is the the disjoint union of  $(A_1 \cap B)$ , ...,  $(A_n \cap B)$ .
- The second equality is given by
$$P(A_i \cap B) = P(A_i)P(B|A_i).$$

# Question

---

We know that a treasure is located in one of two places, with probabilities  $\beta$  and  $1 - \beta$ , respectively, where  $0 < \beta < 1$ . We search the first place and if the treasure is there, we find it with probability  $p > 0$ .

Show that the event of not finding the treasure in the first place suggests that the treasure is in the second place

Let  $A$  and  $B$  be the events

$A = \{\text{the treasure is in the second place}\}$

$B = \{\text{not find the treasure in the first place}\}$

# Question

---

We know that a treasure is located in one of two places, with probabilities  $\beta$  and  $1 - \beta$ , respectively, where  $0 < \beta < 1$ . We search the first place and if the treasure is there, we find it with probability  $p > 0$ .

Show that the event of not finding the treasure in the first place suggests that the treasure is in the second place

By the total probability theorem

$$\begin{aligned} P(B) &= P(A^c)P(B|A^c) + P(A)P(B|A) \\ &= \beta(1 - p) + (1 - \beta) \end{aligned}$$

# Question

---

We know that a treasure is located in one of two places, with probabilities  $\beta$  and  $1 - \beta$ , respectively, where  $0 < \beta < 1$ . We search the first place and if the treasure is there, we find it with probability  $p > 0$ .

Show that the event of not finding the treasure in the first place suggests that the treasure is in the second place

By the total probability theorem

$$\begin{aligned} P(A|B) &= \frac{P(A \cap B)}{P(B)} = \frac{1 - \beta}{\beta(1 - p) + (1 - \beta)} \\ &= \frac{1 - \beta}{1 - \beta p} > 1 - \beta = P(A) \end{aligned}$$

# Independence

---

- Independent Events

- $A, B$  are independent  $\longleftrightarrow B$  provides no information of  $A$

$$P(A|B) = P(A)$$

- Equivalently

$$P(A \cap B) = P(A)P(B)$$

# Question

---

A hunter has two hunting dogs. On a two-path road, each dog will choose the **correct path** with probability  $p$  independently. Let each dog choose a path, and if they agree, take that one, and if they disagree, randomly pick a path. Is this strategy better than **just letting one of the two dogs decide on a path**?

Both dogs agree on the correct path

$$p \cdot p = p^2$$

The dogs disagree

$$p(1 - p) \cdot 2$$

# Question

---

A hunter has two hunting dogs. On a two-path road, each dog will choose the **correct path** with probability  $p$  independently. Let each dog choose a path, and if they agree, take that one, and if they disagree, randomly pick a path. Is this strategy better than **just letting one of the two dogs decide on a path**?

Hunter chooses the correct path when dogs disagree

$$p(1 - p)$$

The probability that hunter chooses the correct path

$$p^2 + p(1 - p) = p$$

# Question

---

There are  $n$  different power plants. And each one can produce enough electricity to supply the entire city.

Now suppose that the  $i$ th power plants fails independently with probability  $p_i$ .

(a) What is the probability that the city will experience a black-out?

Let  $A$  denote the event that the city experiences a black-out.

Since the power plants fail independently

$$P(A) = \prod_{i=1}^n p_i$$

# Question

---

There are  $n$  different power plants. And each one can produce enough electricity to supply the entire city.

Now suppose that the  $i$ th power plants fails independently with probability  $p_i$ .

(b) Now suppose two power plants are necessary to keep the city from a black-out. Find the probability that the city will experience a black-out.

The city will black out if either all  $n$  or any  $n - 1$  power plants fail

These two events are mutually exclusive

# Question

---

There are  $n$  different power plants. And each one can produce enough electricity to supply the entire city.

Now suppose that the  $i$ th power plants fails independently with probability  $p_i$ .

(b) Now suppose **two** power plants are necessary to keep the city from a black-out. Find the probability that the city will experience a black-out.

$$P(A) = \prod_{i=1}^n p_i + \sum_{i=1}^n \left( (1 - p_i) \prod_{j \neq i} p_j \right)$$

# Thanks

---

Question are welcome.
